(57) **ABSTRACT**

A thin film transistor array panel includes: a gate line disposed on a substrate and including a gate electrode, a semiconductor layer including an oxide semiconductor disposed on the substrate, and a data wire layer disposed on the substrate and including a data line intersecting the gate line, a source electrode connected to the data line, and a drain electrode facing the source electrode. In addition, at least one of the data line, the source electrode or the drain electrode of the data wire layer includes a barrier layer and a main wiring layer disposed on the barrier layer. The main wiring layer includes copper or a copper alloy. Also, the barrier layer includes a metal oxide, and the metal oxide includes zinc.

CROSS-REFERENCE TO RELATED APPLICATION

This application is a divisional of U.S. application Ser. No. 13/660,362 filed on Oct. 25, 2012, which claims priority to Korean Patent Application No. 10-2012-0050177 filed on May 11, 2012, the entire disclosure of which is hereby incorporated by reference herein in its entirety.

(a) TECHNICAL FIELD

The present invention relates to a thin film transistor array panel.

(b) DISCUSSION OF THE RELATED ART

A flat panel display such as, for example, a liquid crystal display, an organic light emitting diode display, or the like may include a plurality of pairs of field generating electrodes and an electro-optical active layer interposed therebetween. The liquid crystal display includes a liquid crystal layer as the electro-optical active layer and the organic light emitting diode display includes an organic emission layer as the electro-optical active layer.

One of a pair of field generating electrodes may be connected to a switching element to receive an electric signal, and the electro-optical active layer may convert the electric signal into an optical signal, thereby displaying an image.

In the flat panel display, a thin film transistor (TFT), which is a three-terminal element, is used as the switching element, and signal lines of a gate line transferring a scanning signal for controlling the thin film transistor, a data line transferring a signal applied to a pixel electrode, and the like are included in the flat panel display.

As the area of the display device has become larger, a method of reducing resistance in signal lines has been researched to implement high-speed driving oxide semiconductor technology. For example, to reduce the resistance of the signal line, a main wiring layer formed of copper or a copper alloy, and a barrier layer made of an oxide semiconductor have been researched in an attempt to prevent the material such as copper from being diffused into the semiconductor layer.

SUMMARY

Exemplary embodiments of the present invention provide a thin film transistor array panel including a barrier layer interposed between a main wiring layer and a semiconductor layer.

Exemplary embodiments of the present invention provide a thin film transistor array panel including a capping layer interposed between a main wiring layer and a passivation layer.

In accordance with an exemplary embodiment of the present invention, a thin film transistor array panel is provided. The thin film transistor array panel includes: a gate line disposed on a substrate and including a gate electrode, a semiconductor layer including an oxide semiconductor disposed on the substrate and a data wire layer disposed on the substrate and including a data line intersecting the gate line, a source electrode connected to the data line, and a drain electrode facing the source electrode. In addition, at least one of the data line, the source electrode or the drain electrode of the data wire layer includes a barrier layer, a main wiring layer

disposed on the barrier layer, and a capping layer disposed on the main wiring layer. The main wiring layer includes copper or a copper alloy. Also, the barrier layer and the capping layer includes a metal oxide, and the metal oxide includes zinc.

The barrier layer may include one of indium-zinc oxide (IZO), gallium-zinc oxide (GZO), or aluminum-zinc oxide (AZO).

The barrier layer may include gallium-zinc oxide (GZO), and an amount of gallium oxide (Ga_2O_3) included in gallium-zinc oxide (GZO) may be in a range from about 2.5 mol % to about 10 mol %.

The barrier layer may include indium-zinc oxide (IZO), and the amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) may be in the range from about 2.5 wt % (about 0.75 mol % or about 1.5 at %) to about 90 wt %.

The barrier layer may include indium-zinc oxide (IZO) and the amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) may be no greater than 65 wt % (about 35.3 mol % or about 52.1 at %), and the barrier layer may be in a polycrystalline state.

The barrier layer may include indium-zinc oxide (IZO), and the amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) may be in a range from about 15 wt % (about 4.9 mol % or about 9.4 at %) to about 65 wt % (about 35.3 mol % or about 52.1 at %).

The barrier layer may include indium-zinc oxide (IZO), and the amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) may be in a range from about 20 wt % (about 6.8 mol % or about 12.8 at %) to about 40 wt % (about 16.4 mol % or about 28.1 at %).

The barrier layer may include indium-zinc oxide (IZO), in which a thickness of the barrier layer including indium-zinc oxide is no greater than 100 nm, and the barrier layer may have an average crystalline grain size of about 10 Å to about 2000 Å.

The barrier layer may include aluminum-zinc oxide (AZO) and the amount of aluminum oxide (Al_2O_3) included in aluminum-zinc oxide (AZO) may be in a range from about 2.5 mol % to about 50 mol %.

The capping layer may include one among indium-zinc oxide (IZO), gallium-zinc oxide (GZO), or aluminum-zinc oxide (AZO).

The capping layer may include gallium-zinc oxide (GZO) and the amount of gallium oxide (Ga_2O_3) included in gallium-zinc oxide (GZO) may be in a range from about 2.5 mol % (about 5.6 wt % or about 4.9 at %) to about 10 mol % (about 20.4 wt % or about 18.2 at %).

The capping layer may include indium-zinc oxide (IZO) and the amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) may be in a range from about 20 wt % (about 6.8 mol % or about 12.8 at %) to about 40 wt % (about 16.4 mol % or about 28.1 at %).

The capping layer may include aluminum-zinc oxide (AZO) and the amount of aluminum oxide (Al_2O_3) included in aluminum-zinc oxide (AZO) may be in a range from about 2.5 mol % to about 50 mol %.

The barrier layer may have conductivity.

The semiconductor layer may have the same planar shape as the source electrode, the drain electrode, and the data line except for a channel portion of the semiconductor layer.

The barrier layer and the main wiring layer may directly contact each other.

The barrier layer is disposed between the main wiring layer and the semiconductor layer.

An etch rate of the barrier layer may be in a range from about 25 Å/s to about 110 Å/s.

3

In accordance with an exemplary embodiment of the present invention, a thin film transistor array panel is provided. The thin film transistor array panel includes a gate line disposed on a substrate and including a gate electrode, a gate insulating layer disposed on the gate line, a semiconductor layer including an oxide semiconductor disposed on the gate insulating layer, wherein the semiconductor layer extends in a longitudinal direction and includes a projection which extends toward the gate electrode and a data line intersecting the gate line, a source electrode connected to the data line, a drain electrode facing the source electrode, a passivation layer disposed on the data line, the drain electrode and on a portion of the projection of the semiconductor layer disposed between the source electrode and the drain electrode, wherein the data line, the source electrode and the drain electrode each include a barrier layer and a main wiring layer disposed on the barrier layer.

The main wiring layer includes a metal or a metal alloy, and the barrier layer and the capping layer includes a metal oxide, wherein the capping layer is in a polycrystalline state.

The barrier layer may include one of indium-zinc oxide (IZO), gallium-zinc oxide (GZO), or aluminum-zinc oxide (AZO).

The capping layer may include indium-zinc oxide (IZO), and wherein the amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) is in a range from about 15 wt % to about 65 wt %.

The capping layer may include indium-zinc oxide (IZO), and wherein the amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) is in a range from about 20 wt % to about 40 wt %.

The passivation layer may include a lower passivation layer which includes silicon oxide and an upper passivation layer which includes silicon nitride disposed on the lower passivation layer, wherein the lower passivation layer directly contacts the barrier layer and the main wiring layer of each of the data line, the source electrode and the drain electrode and wherein the main wiring layer of each of the data line, the source electrode and the drain electrode includes one of copper or a copper alloy.

The data line, the source electrode and the drain electrode each may further include a capping layer disposed between the passivation layer and the main wiring layer and wherein the capping layer of each of the data line, the source electrode and the drain electrode includes one of indium-zinc oxide (IZO), gallium-zinc oxide (GZO), or aluminum-zinc oxide (AZO).

The barrier layer of each of the data line, source electrode and the drain electrode may be disposed directly on the semiconductor layer.

The semiconductor layer may include at least one selected from the group consisting of zinc (Zn), indium (In), tin (Sn), gallium (Ga), and hafnium (Hf).

The semiconductor layer may include indium-gallium-zinc oxide.

The barrier layer of each of the data line, the source electrode and the drain electrode may be in a polycrystalline state.

According to an exemplary embodiment of the present invention, by forming the barrier layer made of the metal oxide, the characteristic deterioration of the thin film transistor by oxidation of the main wiring layer may be prevented, and by controlling the amount of oxide included in the barrier layer, the under-cut of barrier layer may be reduced.

BRIEF DESCRIPTION OF THE DRAWINGS

Exemplary embodiments of the present invention can be understood in more detail from the following detailed description taken in conjunction with the accompanying drawings, in which:

4

FIG. 1 is a top plan view of a thin film transistor array panel according to an exemplary embodiment of the present invention.

FIG. 2 is a cross-sectional view taken along the line II-II of FIG. 1.

FIG. 3 shows an etch rate and an etch profile according to an amount of gallium oxide (Ga_2O_3) in a barrier layer according to an exemplary embodiment of the present invention.

FIG. 4 is a photo showing an under-cut of a barrier layer in a comparative example of the present invention.

FIG. 5 is a photo showing an under-cut of a barrier layer according to an exemplary embodiment of the present invention.

FIG. 6 is a graph showing an etch rate according to an amount of indium oxide (In_2O_3) in a barrier layer according to an exemplary embodiment of the present invention.

FIG. 7 and FIG. 8 show an etch rate and an etch profile according to an amount of indium oxide (In_2O_3) in a barrier layer according to an exemplary embodiment of the present invention.

FIG. 9 is a cross-sectional view of a liquid crystal display according to an exemplary embodiment of the present invention.

DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

Exemplary embodiments of the present invention will be described more fully hereinafter with reference to the accompanying drawings, in which exemplary embodiments of the present invention are shown. However, exemplary embodiments of the present invention are not limited to exemplary embodiments described herein, and may be embodied in other forms.

In the drawings, the thicknesses of layers and regions are exaggerated for clarity. It is to be noted that when a layer is referred to as being "on" another layer or substrate, it can be directly formed on the other layer or substrate or can be formed on the other layer or substrate with an intervening layer or layers interposed therebetween. Like constituent elements are denoted by like reference numerals throughout the specification.

As used herein, the singular forms "a," "an" and "the" are intended to include the plural forms as well, unless the context clearly indicates otherwise.

FIG. 1 is a top plan view of a thin film transistor array panel according to an exemplary embodiment of the present invention. FIG. 2 is a cross-sectional view taken along the line II-II of FIG. 1.

Referring to FIG. 1 and FIG. 2, a thin film transistor array panel according to the present exemplary embodiment includes a plurality of gate lines **121** formed on an insulation substrate **110** made of, for example, transparent glass, quartz, or plastic. Also, in an exemplary embodiment, the insulation substrate **110**, may be formed of, for example, ceramic or silicon materials. Further, in an exemplary embodiment, the insulation substrate **110** may be, for example, a flexible substrate. Suitable materials for the flexible substrate include, for example, polyethersulfone (PES), polyethylenenaphthalate (PEN), polyethylene (PE), polyimide (PI), polyvinyl chloride (PVC), polyethylene terephthalate (PET), or combinations thereof.

Each gate line **121** transmits a gate signal and extends mainly in a transverse direction. Each gate line **121** includes a plurality of gate electrodes **124** protruded from the gate line **121**. For example, the gate line **121** and gate electrodes **124** may be formed of one of aluminum (Al), copper (Cu), molybdenum (Mo), titanium (Ti), nickel (Ni), tungsten (W), gold

(Au), palladium (Pd), platinum (Pt), chromium (Cr), neodymium (Nd), zinc (Zn), cobalt (Co), manganese (Mn) and any mixtures or alloys thereof. In addition, the gate line 121 and gate electrodes 124, may include, for example, a transparent conductive material such as an indium tin oxide (ITO), an indium zinc oxide (IZO) and an aluminum doped zinc oxide (AZO).

For example, in an exemplary embodiment, the gate line 121 and the gate electrode 124 are made of, for example, a triple-layer structure. For example, in an exemplary embodiment the gate line 121 may include a first layer 121p, a second layer 121q and a third layer 121r. In addition, the gate electrode 124 may include, for example, a first layer 124p, a second layer 124q and a third layer 124r. For example, in an exemplary embodiment, the first layers 121p and 124p, the second layers 121q and 124q, and the third layers 121r and 124r may each be made of at least one of an aluminum-based metal such as aluminum (Al), an aluminum alloy, and the like, a silver-based metal such as silver (Ag), a silver alloy, and the like, a copper-based metal such as copper (Cu), a copper alloy, and the like, a molybdenum-based metal such as molybdenum (Mo), a molybdenum alloy, and the like, and chromium (Cr), titanium (Ti), tantalum (Ta), manganese (Mn), and the like.

Also, the first layers 121p and 124p, the second layers 121q and 124q, and the third layers 121r and 124r may be formed by combining layers having different physical properties. In the present exemplary embodiment, the gate line 121 and gate electrode 124 are formed in the triple-layer structure, but exemplary embodiments of the present invention are not limited thereto. Alternatively, for example, the gate line 121 and gate electrode 124 may be formed in a single-layer structure or a double-layer structure.

A gate insulating layer 140 made of an insulating material such as, for example, silicon oxide or silicon nitride is disposed on the gate line 121. For example, the gate insulating layer 140 may be made of, for example, silicon nitride (SiN_x), silicon oxide (SiO_x), silicon oxynitride (SiO_xN_y), aluminum oxide (AlO_x), yttrium oxide (Y₂O₃), hafnium oxide (HfO_x), zirconium oxide (ZrO_x), aluminum nitride (AlN), aluminum oxynitride (AlNO), titanium oxide (TiO_x), barium titanate (BaTiO₃), lead titanate (PbTiO₃), or a combination thereof.

For example, in an exemplary embodiment, the gate insulating layer 140 may include a first insulating layer 140a and a second insulating layer 140b. The first insulating layer 140a may be made of, for example, silicon nitride (SiN_x) with a thickness of about 4000 Å, and the second insulating layer may be made of, for example, silicon oxide (SiO₂) with a thickness of about 500 Å. Alternatively, the first insulating layer 140a may be made of, for example, silicon oxynitride (SiON), and the second insulating layer 140b may be made of, for example, silicon oxide (SiO₂). In the present exemplary embodiment, the gate insulating layer 140 is formed as, for example, a double-layer structure but exemplary embodiments of the present invention are not limited thereto. For example, alternatively, the gate insulating layer may be formed as, for example, a single-layer structure.

A plurality of semiconductor layers 151 made of an oxide semiconductor are formed on the gate insulating layer 140. The semiconductor layers 151 mainly extend in, for example, a longitudinal direction and include a plurality of projections 154 extending toward the gate electrodes 124.

The semiconductor layers 151 include, for example, at least one among zinc (Zn), indium (In), tin (Sn), gallium (Ga), and hafnium (Hf). For example, in the present exemplary embodiment, the semiconductor layers 151 may be indium-gallium-zinc oxide.

A plurality of data lines 171, a plurality of source electrodes 173 connected to the data lines 171, and a plurality of drain electrodes 175 are formed on the semiconductor layer 151 and the gate insulating layer 140.

The data lines 171 transmit a data signal and extend mainly in the longitudinal direction, thereby intersecting the gate lines 121. The source electrodes 173 extend, for example, from the data lines 171 thereby overlapping the gate electrodes 124, and may have a “U” shape.

The drain electrodes 175 are separated from the data lines 171 and extend, for example, toward an upper portion of the “U” shape of the source electrodes 173.

Each of the data lines 171, source electrodes 173, and drain electrodes 175 has, for example, a triple-layer structure including barrier layers. For example, the data lines 171 may include a barrier layer 171p, a main wiring layer 171q and a capping layer 171r. In addition, the source electrodes 173 may include, for example, a barrier layer 173p, a main wiring layer 173q and a capping layer 173r. Moreover, the drain electrodes 175 may include, for example, a barrier layer 175p, a main wiring layer 175q, and a capping layer 175r. For example, the barrier layers 171p, 173p, and 175p are made of a metal oxide, the main wiring layers 171q, 173q, and 175q are made of copper or a copper alloy, and the capping layers 171r, 173r, and 175r are made of a copper alloy or a metal oxide.

For example, the barrier layers 171p, 173p, and 175p may be made of one of indium-zinc oxide, gallium-zinc oxide, and aluminum-zinc oxide, and the capping layers 171r, 173r, and 175r may be made of one of a copper-manganese alloy, indium-zinc oxide, gallium-zinc oxide, and aluminum-zinc oxide.

Hereafter, the barrier layers 171p, 173p, and 175p and the capping layers 171r, 173r, and 175r according to the present exemplary embodiment will be described.

When the barrier layers 171p, 173p, and 175p are made of gallium-zinc oxide (GZO), the amount of gallium oxide (Ga₂O₃) in the entire gallium-zinc oxide (GZO) may be in a range, for example, between about 2.5 mol % to about 10 mol %.

When the barrier layers 171p, 173p, and 175p are made of indium-zinc oxide (IZO), the amount of indium oxide (In₂O₃) in the entire indium-zinc oxide (IZO) may be, for example, in a range between about 2.5 wt % (about 0.75 mol % or about 1.5 at %) to about 90 wt % (about 72.5 mol % or about 84.1 at %). When the amount of indium oxide included in barrier layers 171p, 173p, and 175p is no greater than 2.5 wt %, an under-cut may be seriously generated such that it may be difficult for the barrier layers 171p, 173p and 175p to function as a diffusion preventing layer. Accordingly, 2.5 wt % as a lower limit of the amount of indium oxide is a minimum value to use the barrier layers 171p, 173p and 175p as a diffusion preventing layer between an oxide semiconductor thin film and a thin film including, for example, copper. Also, 90 wt % as an upper limit for the amount of indium oxide included in each of the barrier layers 171p, 173p and 175p may be a maximum value in a range which allows the barrier layers 171p, 173p and 175p to be in a polycrystalline state, although a tailing phenomenon may be generated. If the indium oxide amount is over 90 wt %, patterning of a channel portion may be difficult such that a boundary of the channel portion may be shorted.

Here, when the indium oxide amount is less than about 65 wt %, the barrier layers 171p, 173p, and 175p may be in, for example, a polycrystalline state. When a condition of the polycrystalline state is set up as the upper limit, in an exemplary embodiment of the present invention, the indium oxide

amount included in the barrier layers **171p**, **173p** and **175p** may be in a range, for example, from about 2.5 wt % (about 0.75 mol % or about 1.5 at %) to about 65 wt % (about 35.3 mol % or about 52.1 at %).

For example, the indium oxide amount included in the barrier layers **171p**, **173p** and **175p** may be in the range from about 20 wt % (about 6.8 mol % or about 12.8 at %) to about 40 wt % (about 16.4 mol % or about 28.1 at %). The range of amount of indium oxide is described in further detail with reference to FIG. 6.

When the barrier layers **171p**, **173p** and **175p** are formed of indium-zinc oxide with a thickness of less than about 100 nm, the crystallinity of the barrier layers **171p**, **173p** and **175p** may be confirmed by, for example, a FWHM (full width at half maximum) extraction method using x-ray diffraction (XRD) measurements. For example, in an exemplary embodiment, the barrier layers **171p**, **173p** and **175p** may have an average crystalline grain size of about 10 Å to about 2000 Å.

When the barrier layers **171p**, **173p**, and **175p** are made of aluminum-zinc oxide (AZO), the amount of aluminum oxide (Al_2O_3) in the entire aluminum-zinc oxide (AZO) may be, for example, in the range from about 2.5 mol % to about 50 mol %.

In the present exemplary embodiment, unlike with copper or a copper alloy forming the main wiring layers **171q**, **173q**, and **175q**, by controlling the amount of gallium oxide, indium oxide, or aluminum oxide of the metal oxide included in the barrier layers **171p**, **173p**, and **175p**, the etch rate of the barrier layers **171p**, **173p**, and **175p** may be decreased such that an etch profile of the barrier layers **171p**, **173p**, and **175p** may be increased. For example, by increasing the amount of gallium oxide, indium oxide, or aluminum oxide among the entire metal oxide forming the barrier layers **171p**, **173p**, and **175p**, the etch rate of the barrier layers **171p**, **173p**, and **175p** is decreased such that the under-cut of the barrier layers **171p**, **173p**, and **175p** may be minimized.

When the capping layers **171r**, **173r**, and **175r** are formed of one among indium-zinc oxide, gallium-zinc oxide, and aluminum-zinc oxide, the same range of the barrier layers **171p**, **173p**, and **175p** may be selected such that the characteristic of the thin film transistor may be increased.

When the capping layers **171r**, **173r**, and **175r** are made of indium-zinc oxide (IZO), the amount of indium oxide (In_2O_3) in the entire indium-zinc oxide (IZO) may be, for example, in a range between about 2.5 wt % (about 0.75 mol % or about 1.5 at %) to about 90 wt % (about 72.5 mol % or about 84.1 at %). When the amount of indium oxide included in the capping layers **171r**, **173r**, and **175r** is no greater than 2.5 wt %, an under-cut may be seriously generated such that it may be difficult for the capping layers **171r**, **173r**, and **175r** to function as a diffusion preventing layer. Accordingly, 2.5 wt % as a lower limit of the amount of indium oxide is a minimum value to use the barrier layers **171p**, **173p** and **175p** as a diffusion preventing layer between an oxide semiconductor thin film and a thin film including, for example, copper. Also, 90 wt % as an upper limit for the amount of indium oxide included in each of the capping layers **171r**, **173r**, and **175r** may be a maximum value in a range which allows the capping layers **171r**, **173r**, and **175r** to be in a polycrystalline state, although a tailing phenomenon may be generated. If the indium oxide amount is over 90 wt %, patterning of a channel portion may be difficult such that a boundary of the channel portion may be shorted.

Here, when the indium oxide amount is less than about 65 wt %, the capping layers **171r**, **173r**, and **175r** may be in, for example, a polycrystalline state. When a condition of the

polycrystalline state is set up as the upper limit, in an exemplary embodiment of the present invention, the indium oxide amount included in the capping layers **171r**, **173r**, and **175r** may be in a range, for example, from about 2.5 wt % (about 0.75 mol % or about 1.5 at %) to about 65 wt % (about 35.3 mol % or about 52.1 at %).

For example, the indium oxide amount included in the barrier layers **171p**, **173p** and **175p** may be in the range from about 20 wt % (about 6.8 mol % or about 12.8 at %) to about 40 wt % (about 16.4 mol % or about 28.1 at %).

The capping layers **171r**, **173r**, and **175r** are formed of the metal oxide instead of a conventional copper manganese material such that a slope (sub-threshold slope; S.S.) value after a threshold voltage is decreased in a voltage-current graph representing the characteristic of the thin film transistor. Accordingly, the characteristic of the thin film transistor may be increased.

Alternatively, in an exemplary embodiment, the capping layers **171r**, **173r**, and **175r** may be omitted such that the data line **171** and the drain electrode **175** may be formed as, for example, a double-layer structure including the barrier layers **171p**, **173p**, and **175p** and the main wiring layers **171q**, **173q**, and **175q**.

The projection **154** of the semiconductor layer **151** includes, for example, an exposed portion that is covered by the data line **171** and the drain electrode **175** between the source electrode **173** and the drain electrode **175**. The semiconductor layer **151** may have, for example, substantially the same plane pattern as the data line **171** and the drain electrode **175** except for the exposed portion of the projection **154**.

One gate electrode **124**, one source electrode **173**, and one drain electrode **175** form one thin film transistor (TFT) along with the projection **154** of the semiconductor layer **151**. In addition, the channel of the thin film transistor is formed in the projection **154** between the source electrode **173** and the drain electrode **175**.

A passivation layer **180** is formed on the data line **171**, the drain electrode **175**, and the exposed projection **154** of the semiconductor layer **151**. The passivation layer **180** may be made of, for example, an inorganic insulator such as silicon nitride or silicon oxide, an organic insulator, and a low dielectric ratio insulator. For example, the passivation layer **180** may be formed of an organic insulator such as polyimide, polyamide, acrylic resin, epoxy resin, cyclo-olefin resin, or BCB (benzocyclobutene).

In the present exemplary embodiment, the passivation layer **180** may include, for example, a lower passivation layer **180a** and an upper passivation layer **180b**. For example, the lower passivation layer **180a** may be formed of silicon oxide, and the upper passivation layer **180b** may be formed of silicon nitride.

When depositing the passivation layer **180** formed of silicon oxide, the main wiring layers **171q**, **173q**, and **175q** formed with copper directly contact the passivation layer **180** such that lifting is generated by copper oxide (CuOx) generated through contact thereof, or corrosion may be generated when forming a contact hole **185** in the passivation layer **180**. The contact hole **185** formed in the passivation layer **180** is discussed in further detail below. However, according to the present exemplary embodiment, the capping layers **171r**, **173r**, and **175r** are positioned under the passivation layer **180** such that the lifting and the corrosion of the data line **171** and the drain electrode **175** may be prevented. In addition, as described above, by controlling the amount of gallium oxide, indium oxide, or aluminum oxide of the metal oxide included in the capping layers **171r**, **173r**, and **175r**, the under-cut of the capping layers **171r**, **173r**, and **175r** may be minimized,

thereby increasing the etch profile. Accordingly, the characteristics of the thin film transistor may be increased.

The passivation layer **180** has a plurality of contact holes **185** exposing one end of the drain electrodes **175**.

A plurality of pixel electrodes **191** are formed on the passivation layer **180**. Each pixel electrode **191** is physically and electrically connected to a drain electrode **175** through a contact hole **185** thereby receiving a data voltage from a drain electrode **175**.

The pixel electrode **191** may be made of a transparent conductor such as, for example, indium tin oxide (ITO), indium zinc oxide (IZO), aluminum zinc oxide (AZO), cadmium tin oxide (CTO), or a reflective electric conductor such as, for example, aluminum (Al), gold (Au), silver (Ag), copper (Cu), iron (Fe), titanium (Ti), tantalum (Ta), molybdenum (Mo), rubidium (Rb), tungsten (W), and alloys, or combinations thereof. In addition, the pixel electrode **191** can be formed of, for example, transfective materials or a combination of transparent materials and reflective materials.

Next, the amount of the metal oxide forming the barrier layers **171p**, **173p** and **175p** according to an exemplary embodiment of the present invention will be described.

FIG. 3 shows an etch rate and an etch profile according to an amount of gallium oxide (Ga_2O_3) in a barrier layer according to an exemplary embodiment of the present invention.

Referring to FIG. 3, the barrier layers **171p**, **173p** and **175p** are formed of, for example, gallium-zinc oxide in accordance with the exemplary embodiment according to FIG. 1 and FIG. 2, and an etch speed and an etch profile of the barrier layers **171p**, **173p** and **175p** are shown while increasing the amount of gallium oxide (Ga_2O_3) included in the gallium-zinc oxide.

Firstly, when the amount of gallium oxide is about 2.3 wt %, the etch speed is about 613 Å/s which is a very large etch speed, and the under-cut of the barrier layers **171p**, **173p** and **175p** is serious for the etch profile. As the amount of gallium oxide is gradually increased from about 5.6 wt % (about 2.5 mol %), to about 8.8 wt %, and to about 11.8 wt % (about 5.0 mol %), the etch speed of the barrier layers **171p**, **173p** and **175p** is decreased and the under-cut is reduced.

When the barrier layers **171p**, **173p** and **175p** according to an exemplary embodiment of the present invention are formed of gallium-zinc oxide, the amount of gallium oxide included in each of the barrier layers **171p**, **173p** and **175p** may be in the range from, for example, about 2.5 mol % (about 5.6 wt %) to about 10 mol %. When the amount of gallium oxide is less than about 2.5 mol % (about 5.6 wt %), the under-cut is seriously generated. Moreover, when the amount gallium oxide is larger than about 10 mol %, the tailing of the barrier layers **171p**, **173p** and **175p** is seriously generated such that the channel may be shorted.

FIG. 4 is a photo showing an under-cut of a barrier layer in a comparative example of the present invention. FIG. 5 is a photo showing an under-cut of a barrier layer according to an exemplary embodiment of the present invention.

Referring to FIG. 4 and FIG. 5, it is noted that when the amount of gallium oxide (Ga_2O_3) included in each of the barrier layers **171p**, **173p** and **175p** made of gallium-zinc oxide is about 5.6 wt % (2.5 mol %), the under-cut of the barrier layers **171p**, **173p** and **175p** is generated at about 0.1 µm. Also, when the amount of gallium oxide (Ga_2O_3) included in each of the barrier layers **171p**, **173p** and **175p** is about 11.8 wt % (about 5.0 mol %), the under-cut of the barrier layers **171p**, **173p** and **175p** is generated at about 0.06 µm. Accordingly, compared with the comparative example, in an exemplary embodiment of the present invention, the

under-cut of the barrier layers **171p**, **173p** and **175p** is reduced by about 40% and the etch profile of the barrier layers **171p**, **173p** and **175p** is increased.

FIG. 6 is a graph showing an etch rate according to an amount of indium oxide (In_2O_3) in a barrier layer according to an exemplary embodiment of the present invention.

Referring to FIG. 6, the barrier layers **171p**, **173p** and **175p** are formed of, for example, indium-zinc oxide in accordance with the exemplary embodiment according to FIG. 1 and FIG. 2, and the etch speed of the barrier layers **171p**, **173p** and **175p** is shown while the amount of indium oxide (In_2O_3) included in indium-zinc oxide is gradually increased.

As the amount of indium oxide (In_2O_3) included in the barrier layers **171p**, **173p** and **175p** is increased, the etch speed (etch rate) of the barrier layers **171p**, **173p** and **175p** is gradually decreased. If the etch speed is larger than about 110 Å/s, the under-cut of the barrier layers **171p**, **173p** and **175p** may be generated, and if the etch speed is less than about 25 Å/s, the tailing may be generated.

The amount of the indium oxide corresponding to the etch speed of about 110 Å/s is about 20 wt %. However, when considering an error that may be generated according to a change in the etching conditions, the lower limit of the indium oxide amount may be set as, for example, about 15 wt %, and the upper limit of the indium oxide amount may be set as, for example, about 65 wt %. The upper limit of about 65 wt % for the amount of indium oxide represents the maximum amount of indium oxide which may be included in the barrier layers **171p**, **173p** and **175p** and still have the barrier layers **171p**, **173p** and **175p** in a polycrystalline state. Accordingly, when the barrier layers **171p**, **173p** and **175p** according to an exemplary embodiment of the present invention are formed of indium-zinc oxide, the amount of indium oxide included in the barrier layers **171p**, **173p** and **175p** may be in the range, for example, from about 15 wt % (about 4.9 mol % or about 9.4 at %) to about 65 wt % (about 35.3 mol % or about 52.1 at %). For example, in an exemplary embodiment of the present invention, the indium oxide may be included in the barrier layers **171p**, **173p** and **175p** in a range between about 20 wt % (about 6.8 mol % or about 12.8 at %) and about 40 wt % (about 16.4 mol % or about 28.1 at %) corresponding to the boundary of the above-described etch speed.

FIG. 7 and FIG. 8 show an etch rate and an etch profile according to an amount of indium oxide (In_2O_3) in a barrier layer according to an exemplary embodiment of the present invention.

Referring to FIG. 7 and FIG. 8, when the amount of indium oxide (In_2O_3) is about 10 wt %, the under-cut of the barrier layers **171p**, **173p** and **175p** is serious. In addition, as the amount of indium oxide (In_2O_3) is increased, the under-cut of the barrier layers **171p**, **173p** and **175p** may be decreased. However, if the amount of indium oxide (In_2O_3) is very large such that the etch rate is decreased, the tailing may appear.

As described above, if the under-cut of the barrier layers **171p**, **173p** and **175p** disposed under the main wiring layers **171q**, **173q** and **175q** formed of the copper or copper alloy is generated, a void is largely generated according to oxidation of the main wiring layers **171q**, **173q** and **175q** such that the channel portion may be deteriorated. For example, an edge portion of the source electrode **173** and the drain electrode **175** formed with the material including copper is oxidized by the layer of silicon oxide contacted thereto such that the channel characteristic of the thin film transistor may be deteriorated. However, this difficulty may be prevented by forming the barrier layers **171p**, **173p** and **175p** of a metal oxide such as indium-zinc oxide (IZO), gallium-zinc oxide (GZO), or aluminum-zinc oxide (AZO).

11

When the capping layers **171r**, **173r** and **175r**, are formed using conventional copper manganese material, the capping layers **171r**, **173r** and **175r** are oxidized by the passivation layer **180** formed of silicon oxide adjacent thereto such that the characteristics of the thin film transistor may be affected. However, this difficulty may be prevented by forming the capping layers **171r**, **173r** and **175r** of a metal oxide such as indium-zinc oxide (IZO), gallium-zinc oxide (GZO), or aluminum-zinc oxide (AZO). Also, by controlling the amount of the oxide included in the capping layers **171r**, **173r** and **175r**, the etch profile may be increased.

The barrier layers **171p**, **173p** and **175p** may function as an ohmic contact while preventing the copper diffusion. Accordingly, the barrier layers **171p**, **173p** and **175p** should not be formed of the oxide semiconductor like the semiconductor layer **151** forming the channel.

A thin film transistor array panel having the semiconductor layer **151** made of the oxide semiconductor including indium, zinc, or tin was described. Next, referring to FIG. 9, a liquid crystal display including the thin film transistor array panel **100** according to the present exemplary embodiment will be described.

FIG. 9 is a cross-sectional view of a liquid crystal display according to an exemplary embodiment of the present invention.

Referring to FIG. 9, a second substrate **210** facing the first substrate **110** is disposed. The second substrate **210** may be an insulation substrate made of, for example, transparent glass, quartz or plastic. Also, in an exemplary embodiment, the second substrate **210**, may be formed of, for example, ceramic or silicon materials. Further, in an exemplary embodiment, the second substrate **210** may be, for example, a flexible substrate. Suitable materials for the flexible substrate may include, for example, polyethersulfone (PES), polyethylenephthalate (PEN), polyethylene (PE), polyimide (PI), or polyvinyl chloride.

A light blocking member **220** is formed on the second substrate **210**. The light blocking member **220** is referred to as a black matrix and prevents light leakage. The light blocking member **220** may be formed of a light-shielding material such as, for example, chrome (Cr), or an acrylic resin formed by mixing carbon with a metal oxide material. Alternatively, in an exemplary embodiment, the blocking member **220** may be omitted.

A plurality of color filters **230** are formed on the second substrate **210** and the light blocking member **220**. Most of the color filters **230** are disposed in the regions enclosed by the light blocking members **220**, and may be extended according to the column direction of the pixel electrodes **191**. Each color filter **230** may display, for example, one among three primary colors such as the primary colors red, green, and blue. However, exemplary embodiments of the present invention are not limited to the three primary colors such as red, green, and blue. For example, alternatively, the color filter **230** may display, for example, one of cyan, magenta, yellow, and white-based colors.

The light blocking member **220** and the color filter **230** are formed, for example, on an opposed display panel **200**. Alternatively, for example, at least one of the light blocking member **220** and the color filter **230** may be formed on the thin film transistor array panel **100**.

An overcoat **250** is formed on the color filter **230** and the light blocking member **220**. The overcoat **250** may be made of, for example, an (organic) insulator, and prevents the color filter **230** from being exposed and provides a flat surface. For example, in an exemplary embodiment, the overcoat **250** may be formed of an (organic) insulator such as benzocyclobutene

12

(BCB) or acrylic resin. Alternatively, for example, in an exemplary embodiment, the overcoat **250** may be omitted.

A common electrode **270** is formed on the overcoat **250**. The common electrode **270** may be made of, for example, a transparent conductive material such as ITO (indium tin oxide), IZO (indium zinc oxide), aluminum zinc oxide (AZO), or cadmium tin oxide (CTO).

The pixel electrode **191** applied with the data voltage forms an electric field along with the common electrode **270** applied with the common voltage such that liquid crystal molecules **31** of the liquid crystal layer **3** between the pixel electrode **191** and the common electrode **270** are rearranged. The pixel electrode **191** and the common electrode **270** form a capacitor to maintain an applied voltage even after a thin film transistor is turned off.

The pixel electrode **191** overlaps a storage electrode line (not shown) to form a storage capacitor, thereby increasing the voltage storage capacity of a liquid crystal capacitor.

In addition, for example, in exemplary embodiments, an alignment layer (not shown) may be formed on at least one of the thin film transistor array panel **100** and the opposed display panel **200** for aligning liquid crystal molecules **31** in the liquid crystal layer **3** in a desired direction.

A thin film transistor array panel according to the present exemplary embodiment is discussed above as being applied to a liquid crystal display, but the present exemplary embodiment may also be widely applied to, for example, display devices performing a switching operation using an organic light emitting diode display and other thin film transistors.

Having described exemplary embodiments of the present invention, it is further noted that it is readily apparent to those of ordinary skill in the art that various modifications may be made without departing from the spirit and scope of the invention which is defined by the metes and bounds of the appended claims.

What is claimed is:

1. A thin film transistor array panel comprising:

a gate line disposed on a substrate and including a gate electrode;

a gate insulating layer disposed on the gate line;

a semiconductor layer including an oxide semiconductor disposed on the gate insulating layer, wherein the semiconductor layer extends in a longitudinal direction and includes a projection which extends toward the gate electrode; and

a data line intersecting the gate line;

a source electrode connected to the data line;

a drain electrode facing the source electrode, and

a passivation layer disposed on the data line, the drain electrode and on a portion of the projection of the semiconductor layer disposed between the source electrode and the drain electrode,

wherein the data line, the source electrode and the drain electrode each include a barrier layer, a main wiring layer disposed on the barrier layer, and a capping layer disposed on the main wiring layer,

wherein the main wiring layer includes a metal or a metal alloy,

wherein the barrier layer and the capping layer includes a metal oxide, and

wherein the capping layer is in a polycrystalline state.

2. The thin film transistor of claim 1, wherein the barrier layer includes one of indium-zinc oxide (IZO), gallium-zinc oxide (GZO), or aluminum-zinc oxide (AZO).

3. The thin film transistor of claim 1, wherein the capping layer includes indium-zinc oxide (IZO), and wherein the

13

amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) is in a range from about 15 wt % to about 65 wt %.

4. The thin film transistor array panel of claim 3, wherein the capping layer includes indium-zinc oxide (IZO), and wherein the amount of indium oxide (In_2O_3) included in indium-zinc oxide (IZO) is in a range from about 20 wt % to about 40 wt %.

5. The thin film transistor of claim 1, wherein the passivation layer includes a lower passivation layer which includes silicon oxide and an upper passivation layer which includes silicon nitride disposed on the lower passivation layer, wherein the lower passivation layer directly contacts the barrier layer and the main wiring layer of each of the data line, the source electrode and the drain electrode and wherein the main wiring layer of each of the data line, the source electrode and the drain electrode includes one of copper or a copper alloy.

14

6. The thin film transistor of claim 5,

wherein the data line, the source electrode and the drain electrode each further include a capping layer disposed between the passivation layer and the main wiring layer and

wherein the capping layer of each of the data line, the source electrode and the drain electrode includes at least one of indium-zinc oxide (IZO), gallium-zinc oxide (GZO), or aluminum-zinc oxide (AZO).

7. The thin film transistor of claim 1, wherein the barrier layer of each of the data line, source electrode and the drain electrode is disposed directly on the semiconductor layer.

8. The thin film transistor of claim 1, wherein the semiconductor layer includes at least one of zinc (Zn), indium (In), tin (Sn), gallium (Ga), and hafnium (Hf).

9. The thin film transistor of claim 8, wherein the semiconductor layer includes indium-gallium-zinc oxide.

10. The thin film transistor of claim 9, wherein the barrier layer of each of the data line, the source electrode and the drain electrode is in a polycrystalline state.
